Why do we have numerical problems in physics ?

One of the major objectives of involving learners in solving problems in teaching-learning process is to promote a more active learning and hence improve conceptual understanding

solving problems in physics

Any easy way to solve problems in physics ?

There is no single prescription which can help in solving each and every problem in physics

Most of the problems can be attempted if you follow certain steps in a sequence.

Simple Steps

1. Understand the problem

(a) Classify the problem by its method of solution.

(b) Summarise the situation with a diagram.

(c) Keep the goal in sight (perhaps by writing it down).

2. Execution tactics

- (a) Work with symbols.
- (b) Keep packets of related variables together
- (c) Be neat and organised.
- (d) Keep it simple.

3. Answer checking

- (a) Dimensionally consistent?
- (b) Numerically reasonable(including sign)?
- (c) Algebraically possible? (Example: no imaginary or infinite answers)
- (d) Functionally reasonable? (Example: greater range with greater initial speed)
- (e) Check special cases and symmetry.
- (f) Report numbers with units specified and with reasonable significant figures.

Example

Area of a rectangular sheet

The length and breadth of a rectangular sheet are 16.2 cm and 10.1cm, respectively. The area of the sheet in appropriate significant figures and error is

(a) $164 \pm 3 \text{ cm}^2$

(b) $163.62 \pm 2.6 \text{ cm}^2$

(c) $163.6 \pm 2.6 \text{ cm}^2$

(d) $163.62 \pm 3 \text{ cm}^2$

Answer (a) is correct

Let us remember Rules for determining the uncertainty in the Results of arithmetic calculations

If the length and breadth of a thin rectangular sheet are measured using a meter scale

And length is

$$\begin{aligned}l &= 16.2 \pm 0.1 \text{ cm} \\ &= 16.2 \text{ cm} \pm 0.6\%\end{aligned}$$

How did we get $\pm 0.6\%$?

As the length is measured by a meter scale the least count = 0.1 cm hence relative error

$$\delta l = \frac{0.1}{16.2} = 0.00617$$

Now the corresponding percentage error can be obtained by multiplying the relative error by 100

Which in this case is 0.6 %

For breadth b

$$b = 10.1 \pm 0.1 \text{ cm} = 10.1 \text{ cm} \pm 1\%$$

Area of the plate = $l \times b$

$$l \times b = 163.62 \text{ cm}^2 \pm 1.6\%$$

Or

$$l \times b = 163.62 \pm 2.6 \text{ cm}^2$$

How is $\pm 1.6\%$ *is equivalent to* 2.6 cm^2 ?

- $\delta A = \frac{\text{percentage error} \times \text{value of area}}{100}$

- $\delta A = \frac{1.6 \times 163.2}{100} = 2.6 \text{ cm}^2$

- The result may be written as area = $164 \pm 3 \text{ cm}^2$

- This is the uncertainty or error in the estimation of area of the rectangular sheet

But why not $163.6 \pm 2.6 \text{ cm}^2$?

- Though looks more accurate we reject it because the estimated area is 164 cm^2
- The error is also rounded off
